New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation's website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we've broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We've also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I'm looking forward to future milestones.

With that in mind I've introduced the theme of the "30 year horizon". We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How can we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The "30 year horizon" is much nearer than it appears.

Tim Daly
CAISS, City College of New York
November 10, 2003 ((iHy))

0.1 Makefile

This book is actually a literate program[2] and can contain executable source code. In particular, the Makefile for this book is part of the source of the book and is included below. Axiom uses the “noweb” literate programming system by Norman Ramsey[6].

Chapter 1

Compiler top level

1.1 `)compile`

This is the implementation of the `)compile` command.

You use this command to invoke the new Axiom library compiler or the old Axiom system compiler. The `)compile` system command is actually a combination of Axiom processing and a call to the Aldor compiler. It is performing double-duty, acting as a front-end to both the Aldor compiler and the old Axiom system compiler. (The old Axiom system compiler was written in Lisp and was an integral part of the Axiom environment. The Aldor compiler is written in C and executed by the operating system when called from within Axiom.)

User Level Required: compiler

Command Syntax:

```
)compile
)compile fileName
)compile fileName.spad
)compile directory/fileName.spad
)compile fileName )old
)compile fileName )translate
)compile fileName )quiet
)compile fileName )noquiet
)compile fileName )moreargs
)compile fileName )onlyargs
```

```

)compile fileName )break
)compile fileName )nobreak
)compile fileName )library
)compile fileName )nolibrary
)compile fileName )vartrace
)compile fileName )constructor nameOrAbbrev

```

These command forms invoke the Aldor compiler.

```

)compile fileName.as
)compile directory/fileName.as
)compile fileName.ao
)compile directory/fileName.ao
)compile fileName.al
)compile directory/fileName.al
)compile fileName.lsp
)compile directory/fileName.lsp
)compile fileName )new

```

Command Description:

The first thing `)compile` does is look for a source code filename among its arguments. Thus

```

)compile mycode.spad
)compile /u/jones/mycode.spad
)compile mycode

```

all invoke `)compiler` on the file `/u/jones/mycode.spad` if the current Axiom working directory is `/u/jones`. (Recall that you can set the working directory via the `)cd` command. If you don't set it explicitly, it is the directory from which you started Axiom.)

If you omit the file extension, the command looks to see if you have specified the `)new` or `)old` option. If you have given one of these options, the corresponding compiler is used.

The command first looks in the standard system directories for files with extension `.as`, `.ao` and `.al` and then files with extension `.spad`. The first file found has the appropriate compiler invoked on it. If the command cannot find a matching file, an error message is displayed and the command terminates.

The first thing `)compile` does is look for a source code filename among its arguments. Thus

```
)compile mycode
)co mycode
)co mycode.spad
```

all invoke `)compiler` on the file `/u/jones/mycode.spad` if the current Axiom working directory is `/u/jones`. Recall that you can set the working directory via the `)cd` command. If you don't set it explicitly, it is the directory from which you started Axiom.

This is frequently all you need to compile your file.

This simple command:

1. Invokes the Spad compiler and produces Lisp output.
2. Calls the Lisp compiler if the compilation was successful.
3. Uses the `)library` command to tell Axiom about the contents of your compiled file and arrange to have those contents loaded on demand.

Should you not want the `)library` command automatically invoked, call `)compile` with the `)nolibrary` option. For example,

```
)compile mycode )nolibrary
```

By default, the `)library` system command *exposes* all domains and categories it processes. This means that the Axiom interpreter will consider those domains and categories when it is trying to resolve a reference to a function. Sometimes domains and categories should not be exposed. For example, a domain may just be used privately by another domain and may not be meant for top-level use. The `)library` command should still be used, though, so that the code will be loaded on demand. In this case, you should use the `)nolibrary` option on `)compile` and the `)noexpose` option in the `)library` command. For example,

```
)compile mycode )nolibrary
)library mycode )noexpose
```

Once you have established your own collection of compiled code, you may find it handy to use the `)dir` option on the `)library` command. This causes `)library` to process all compiled code in the specified directory. For example,

```
)library )dir /u/jones/quantum
```

You must give an explicit directory after `)dir`, even if you want all compiled code in the current working directory processed, e.g.

```
)library )dir .
```

1.1.1 Spad compiler

This command compiles files with file extension `.spad` with the Spad system compiler.

The `)translate` option is used to invoke a special version of the old system compiler that will translate a `.spad` file to a `.as` file. That is, the `.spad` file will be parsed and analyzed and a file using the new syntax will be created.

By default, the `.as` file is created in the same directory as the `.spad` file. If that directory is not writable, the current directory is used. If the current directory is not writable, an error message is given and the command terminates. Note that `)translate` implies the `)old` option so the file extension can safely be omitted. If `)translate` is given, all other options are ignored. Please be aware that the translation is not necessarily one hundred percent complete or correct. You should attempt to compile the output with the Aldor compiler and make any necessary corrections.

You can compile category, domain, and package constructors contained in files with file extension `.spad`. You can compile individual constructors or every constructor in a file.

The full filename is remembered between invocations of this command and `)edit` commands. The sequence of commands

```
)compile matrix.spad
)edit
)compile
```

will call the compiler, edit, and then call the compiler again on the file **matrix.spad**. If you do not specify a *directory*, the working current directory is searched for the file. If the file is not found, the standard system directories are searched.

If you do not give any options, all constructors within a file are compiled. Each constructor should have an `)abbreviation` command in the file in which it is defined. We suggest that you place the `)abbreviation` commands at the top of the file in the order in which the constructors are defined.

The `)library` option causes directories containing the compiled code for each constructor to be created in the working current directory. The name of such a directory consists of the constructor abbreviation and the `.nrlib` file extension. For example, the directory containing the compiled code for the **MATRIX** constructor is called **MATRIX.nrlib**. The `)nolibrary` option says that such files should not be created. The default is `)library`. Note that the semantics of `)library` and `)nolibrary` for the new Aldor compiler and for the old system compiler are completely different.

The `)vartrace` option causes the compiler to generate extra code for the constructor to support conditional tracing of variable assignments. (see ?? on page ??). Without this option, this code is suppressed and one cannot use the

)vars option for the trace command.

The)constructor option is used to specify a particular constructor to compile. All other constructors in the file are ignored. The constructor name or abbreviation follows)constructor. Thus either

```
)compile matrix.spad )constructor RectangularMatrix
```

or

```
)compile matrix.spad )constructor RMATRIX
```

compiles the RectangularMatrix constructor defined in **matrix.spad**.

The)break and)nobreak options determine what the spad compiler does when it encounters an error.)break is the default and it indicates that processing should stop at the first error. The value of the)set break variable then controls what happens.

Given the top level command:

```
)co PR
```

The default call chain looks like:

```
1> (|compiler| (PR))
2> (|compileSpad2Cmd| ("/research/test/int/algebra/PR.spad"))
3> (|compilerDoit| NIL (|rq| |lib|))
4> (/RF-1 NIL)
5> (SPAD "/research/test/int/algebra/PR.spad")
6> (S-PROCESS (|where| ...
7> (|compTopLevel| (|where| (DEF ...
8> (|compOrCroak| (|where| (DEF ...
9> (|compOrCroak| (CATEGORY |domain| ...
<9 (|compOrCroak| ((|DomainSubstitutionMacro| # #) ...
...
10> (|compOrCroak| (|FreeModule| R E) |$EmptyMode| ((#)))
<10 (|compOrCroak| ((|FreeModule| R E) (|Join| # # #) (#)))
...
11> (|compOrCroak| (|construct| (|construct| # #)) $ ((#)))
<11 (|compOrCroak| ((LIST #) $ (#)))
...
<9 (|compOrCroak| ((PROGN ... $) #1=(|Join| # #) (#)))
<8 (|compOrCroak| (|PolynomialRing| (|Mapping| ...
<7 (|compTopLevel| (|PolynomialRing| ...
<6 (S-PROCESS NIL)
<5 (SPAD T)
<4 (/RF-1 T)
<3 (|compilerDoit| T)
(1) ->
```

1.1.2 Aldor compiler

This command compiles files with file extensions *.as*, *.ao* and *.al* with the Aldor compiler. It also can compile files with file extension *.lsp*. These are assumed to be Lisp files generated by the Aldor compiler.

The general description of Aldor command line arguments is in the Aldor documentation. The default options used by the `)compile` command can be viewed and set using the `)set compiler args` Axiom system command. The current defaults are

```
-O -Fasy -Fao -Flsp -laxiom -Mno-AXL_WillObsolete -DAxiom
```

These options mean:

- `-O`: perform all optimizations,
- `-Fasy`: generate a *.asy* file,
- `-Fao`: generate a *.ao* file,
- `-Flsp`: generate a *.lsp* (Lisp) file,
- `-laxiom`: use the axiom library *libaxiom.al*,
- `-Mno-AXL_WillObsolete`: do not display messages about older generated files becoming obsolete, and
- `-DAxiom`: define the global assertion *Axiom* so that the Aldor libraries for generating stand-alone code are not accidentally used with Axiom.

To supplement these default arguments, use the `)moreargs` option on `)compile`. For example,

```
)compile mycode.as )moreargs "-v"
```

uses the default arguments and appends the `-v` (verbose) argument flag. The additional argument specification **must be enclosed in double quotes**.

To completely replace these default arguments for a particular use of `)compile`, use the `)onlyargs` option. For example,

```
)compile mycode.as )onlyargs "-v -O"
```

only uses the `-v` (verbose) and `-O` (optimize) arguments. The argument specification **must be enclosed in double quotes**. In this example, Lisp code is not produced and so the compilation output will not be available to Axiom.

To completely replace the default arguments for all calls to `)compile` within your Axiom session, use `)set compiler args`. For example, to use the above arguments for all compilations, issue

```
)set compiler args "-v -0"
```

Make sure you include the necessary `-l` and `-Y` arguments along with those needed for Lisp file creation. As above, **the argument specification must be enclosed in double quotes**.

The `)compile` command works with several file extensions. We saw above what happens when it is invoked on a file with extension `.as`. A `.ao` file is a portable binary compiled version of a `.as` file, and `)compile` simply passes the `.ao` file onto Aldor. The generated Lisp file is compiled and `)library` is automatically called, just as if you had specified a `.as` file.

A `.al` file is an archive file containing `.ao` files. The archive is created (on Unix systems) with the `ar` program. When `)compile` is given a `.al` file, it creates a directory whose name is based on that of the archive. For example, if you issue

```
)compile mylib.al
```

the directory `mylib.axldir` is created. All members of the archive are unarchived into the directory and `)compile` is called on each `.ao` file found. It is your responsibility to remove the directory and its contents, if you choose to do so.

A `.lsp` file is a Lisp source file, generated by Aldor when called with the `-Flsp` option. When `)compile` is used with a `.lsp` file, the Lisp file is compiled and `)library` is called. For Aldor, You must also have present a `.asy` generated from the same source file.

1.1.3 The top level compiler command

```

1.1.4 The Spad compiler top level function

This is the old compiler. Assume we entered from the "compiler" function, so args is a file with file extension .spad.

The \$f and \$m are compiler variables, probably function and mode. [path-name(5) p??]

          (cons val (cons mode (cons e nil))))
        (t (|compOrCroak| x m e))))))

```

Given:

```
CohenCategory(): Category == SetCategory with

kind: (CEExpr) -> Boolean
operand: (CEExpr, Integer) -> CEExpr
numberOfOperand: (CEExpr) -> Integer
construct: (CEExpr, CEExpr) -> CEExpr
```

the resulting call looks like:

```
(|compOrCroak|
  (DEF (|CohenCategory|)
    ((|Category|))
    (NIL)
    (|Join|
      (|SetCategory|)
      (CATEGORY |package|
        (SIGNATURE |kind| ((|Boolean|) |CEExpr|))
        (SIGNATURE |operand| (|CEExpr| |CEExpr| (|Integer|)))
        (SIGNATURE |numberOfOperand| ((|Integer|) |CEExpr|))
        (SIGNATURE |construct| (|CEExpr| |CEExpr| |CEExpr|))))
    |$EmptyMode|
    (((
      (|$DomainsInScope|
        (FLUID . |true|)
        (|special| |$EmptyMode| |$NoValueMode|)))))))
```

This compiler call expects the first argument *x* to be a DEF form to compile, The second argument, *m*, is the mode. The third argument, *e*, is the environment.

1.1.10 defun compOrCroak

[compOrCroak1 p25]

```
<defun compOrCroak>≡
  (defun |compOrCroak| (x m e)
    (|compOrCroak1| x m e nil nil))
```

This results in a call to the inner function with

```
(|compOrCroak1|
  (DEF (|CohenCategory|)
    ((|Category|))
    (NIL)
    (|Join|
      (|SetCategory|)
      (CATEGORY |package|
        (SIGNATURE |kind| ((|Boolean|) |CEpr|))
        (SIGNATURE |operand| (|CEpr| |CEpr| (|Integer|)))
        (SIGNATURE |numberOfOperand| ((|Integer|) |CEpr|))
        (SIGNATURE |construct| (|CEpr| |CEpr| |CEpr|))))
    |$EmptyMode|
    (((
      |$DomainsInScope|
      (FLUID . |true|)
      (|special| |$EmptyMode| |$NoValueMode|))))
  NIL
  NIL
  |comp|)
```

The inner function augments the environment with information from the compiler stack `$compStack` and `$compErrorMessageStack`. Note that these variables are passed in the argument list so they get preserved on the call stack. The calling function gets called for every inner form so we use this implicit stacking to retain the information.

1.1.39 defun Create a list of unbound symbols

We walk argument *u* looking for symbols that are unbound. If we find a symbol we add it to the free list. If it occurs in a prog then it is bound and we remove it from the free list. Multiple instances of a single symbol in the free list are represented by the alist (symbol . count) [freelist p63]
